Abstract

Extraction and/or recovery of chromium (Cr) and nickel (Ni) from textiles industry wastewater by membrane separation using polymer inclusion membranes (PIMs) based on polymer supports polyvinylidene fluoride (PVDF) and polyvinyl pyrrolidone (PVP), with Nitrilotriacetic acid (NTA) as extractive agent (EA). Furthermore, to quantify the PIMs performances, the macroscopic parameters such as the membrane permeability, P , and the initial flux, J_0 , and the microscopic parameters such as the association constant, K_{ass} , and the apparent diffusion coefficient, D^* , were determined based on the Fick's first law and the saturation law of the EA by the substrate (S). Also, to explain the substrate (S) (Cr or Ni) recovery process performed by the membrane, and to elucidate the mechanistic aspects, the activation parameters such as the energy E_a , the enthalpy $\Delta H^\ddagger$ and the entropy $\Delta S^\ddagger$, were determined. The efficiency of different PIMs to recover Cr and Ni was compared. Respectively, the influence of temperature and pH on removal performance was investigated. The results showed that the macroscopic and microscopic parameters increased with increasing temperature and acidity medium. Similarly, the values of the activation parameters make it possible to explain the membrane performance and to elucidate the mechanism relating to the diffusion of the extracted substrates through this membrane.

1. Introduction

Textile industries, and more particularly dyeing and finishing phases, mainly use harmful chemicals for health, and cause pollution of surface water and groundwater. The use of mordant dyes in these industries is a source of metal pollution since they generally contain functional ligands able to react strongly with chromium, nickel, aluminum, cobalt, copper or iron salts, and to yield different colored complexes with the textile. The wastewater resulting from the dyeing, the finishing and the rinsing phases of the dyed textile fibers, contains large amount of dyes and trace metals such as chromium, nickel, aluminum, cobalt, copper or iron ions. It is therefore essential to treat the textile effluents before their release in the aquatic systems.

Most heavy metals are toxic and harmful to living organisms even at lower concentrations [1], they caused the most serious environmental problems. Faced with increasingly strict regulations, these toxic heavy metals should be removed from wastewater to protect people and the environment. Much has been reported on treatment of heavy metal ions include chemical precipitation [2-3], ion exchange [4], adsorption [5-6], membrane filtration [7], electrochemistry processing technologies [8], etc.

One efficient method to extract and/or to recover trace metals from textiles industry wastewater is based on the use of membrane separation processes. Thus, in the present work, we will focus on the use of polymer inclusion membranes (PIMs) which consist of polymer supports such as polyvinylidene fluoride (PVDF) and polyvinyl pyrrolidone (PVP), and an extractive agent (EA) such as Nitrilotriacetic acid (NTA) (Fig.1). Furthermore, to quantify the PIMs performances, the macroscopic parameters, membrane permeability P , and initial flux J_0 , and the microscopic parameters, association constant K_{ass} , and apparent diffusion coefficient D^* , were determined based on the Fick's first law and a saturation law of the EA by the substrate (S). Also, to explain the substrate (S) (Cr or Ni) recovery process performed by the membrane, and to elucidate the mechanistic aspects, the activation parameters, energy E_a , enthalpy $\Delta H^\ddagger$ and the entropy $\Delta S^\ddagger$, were determined. The efficiencies, of different PIMs to recover Cr and Ni, were compared. In addition, the influence of the temperature and the pH factors on the removal performance was also investigated.

2. Material and Methods

2.1. Calculations

Permeability P and initial flux J_0 are calculated from the following relationships [9-10] :

$$P(t-t_L) = (\ell \cdot V / 2 \cdot S) \ln(C_0 / C_0 - 2C_T) \quad (1)$$

$$P = a \cdot V \cdot \ell / 2 \cdot S \quad \text{and} \quad J_0 = P \cdot C_0 / \ell \quad (2)$$

a : the slope experimental values of the straight lines $-\ln(C_0 - 2C_T) = f(t)$. ℓ : the membrane thickness. S : the membrane active area in contact with the aqueous solutions. V : the receiving phase volume. The microscopic parameters K_{ass} and D^* are determinate according to the following relationships:

$$1/J_0 = 1/D^* \cdot ((1/[T]_0 \cdot K_{ass} \cdot C_0) + 1/[T]_0) \quad (3)$$

$$K_{ass} = \text{intercept (oo)} / \text{slope (p)} \quad \text{and} \quad D^* = (1/\text{oo}) \cdot (1/[T]_0) \quad (4)$$

With p and OO are slope and intercept experimental values of the straight line $1/J_0 = f(1/C_0)$, $[T]_0$: the fixed total concentration of the extractive agent in the membrane phase.

2.2. Chemicals

All chemicals, reagents, and solvents were pure commercial products (Aldrich, Fluka) of analytical grade. The used polymeric support is Polyvinylidene Fluoride PVDF supplied by Alfa Aesar.

2.3. Extraction experiments

Kinetic studies relating to the studied process were carried out in a device with two feed and receiving glass compartments [10–12]. The adopted membrane was clamped tightly between these compartments, using two Teflon rings. The cell was immersed in a thermostatic bath with magnetic stirring of the two compartments. Aliquots (about 0.1 cm^3 each) of the aqueous receiving phase were withdrawn periodically, analyzed, and their concentrations of the substrate (S) were determined by ultraviolet-visible spectroscopy.

3. Results and discussion

3.1. Characterization of the developed membranes by FTIR

The two synthesized PIM membranes were characterized by FTIR (Fig. 2), one membrane containing only the PVDF as a base polymer, and the second PIM made of a mixture of PVDF, PVP as a base polymer and containing NTA as EA (5% M/M). As can be shown in Fig 2; the peaks observed in the spectrum of the PVDF membrane are characteristics of the polymer, namely: a band at 1404 cm^{-1} assigned to groups CH, a band at 876 cm^{-1} allocated to the vibration of the linear C-C link and bands occurring between 1074 and 1278 cm^{-1} corresponding to the elongation vibrations of the C-F connections. The spectrum of the PVDF membrane-NTA shows that most of the absorption bands are present in the spectrum of the PVDF membrane, with the appearance of a characteristic band of the group C = O and O-H group, present in the molecule of NTA, at 1650 cm^{-1} and at 3350 cm^{-1} .

3.2. Characterization of the elaborated membranes by SEM

The figs. 3 and 4 show the surface and cross-section SEM images of the developed PVDF-NTA membrane. The images clearly show the porous structure relative to an asymmetric and dense membrane.

Fig. 3. SEM image PVDF-NTA cross- section.

Fig. 4. SEM image PVDF-NTA surface.

3.3. Effect of initial substrate concentration C_0 on the extraction of Cr(VI) and Ni(II) ions

For this part, we examined the influence of the substrate initial concentration C_0 , on the evolution of various parameters related to the facilitated extraction process of Cr(VI) and Ni(II) through the PIM membrane (PVDF-NTA) with NTA as extractive agent. The C_0 initial concentration values varied, from 0.5 to 2 g/L and from 3 to 24 g/L, respectively for Cr(VI) and Ni(II) ions, under similar operating conditions (pH=4, $T = 298$ K, support: PVDF). The evolutions of the kinetic function $-\ln(C_0 - 2C_t) = f(t)$, are presented by the figures 5 and 6.

Fig. 5. Evolution of the kinetic function $-\ln(C_0 - 2C_t) = f(t)$ for the facilitated extraction of Cr(VI) for different substrate initial concentrations. [NTA] 0 = 0.00039 M, pH = 4, and $T = 298$ K.

Fig. 6. Evolution of the kinetic function $-\ln(C_0-2C_r) = f(t)$ for the facilitated extraction of Ni(II) for different initial substrate concentrations. [NTA] 0 = 0.0001M, pH = 4, and T = 298 K.

From the graphs depicted in Figs 5 and 6, we clearly see linear straight lines of the variation of $-\ln(C_0-2C_r)$ versus time, for both substrates. From the slopes of these straight lines, the values of P and J_0 parameters were calculated and are presented in Table 1:

Table 1. Influence of extractive agent nature and initial substrate concentration C_0 on the evolution of P and J_0 parameters, pH = 4, and T = 298K

Extractive agent	Initial substrate concentration, C_0 (mol L ⁻¹)	$P \times 10^{-7}$ (cm ² s ⁻¹)	$J_0 \times 10^{-7}$ (mmol cm ² s ⁻¹)
Cr(VI)	0.0068	19.27	12.96
	0.0034	20.22	6.8
	0.0017	21.84	3.67
	0.00085	22.89	1.92
Ni(II)	0.0825	12.59	141.91
	0.0412	14.21	80.06
	0.0206	18.33	51.63
	0.0103	19.40	27.32

All values in Tab. 1 indicate a clear influence of the nature of the extractive agent and a weak influence of the initial substrate concentration, C_0 , on the evolution of P and J_0 parameters compared with the performance of the adopted PIM. However, the PIM-NTA membrane appears to be relatively more efficient for the facilitated extraction process of Cr(VI) compared to its Ni(II) counterpart under the adopted conditions. To establish more accurate interpretations and comparisons of the performance of this membrane type for this oriented process, Line weaver-Burk plots for the function $1/J_0 = f(1/C_0)$ were studied (Figs. 7 and 8), in order to calculate and analyze the evolution of microscopic parameters Kass and D^* to the diffusion and the movement of the substrate across the membrane phase.

Fig. 7. Line weaver - Burk straight for the facilitated extraction phenomenon of Cr(VI) by the PIM (PVDF-NTA) [NTA]₀ = 0.00387M, pH = 4, and T = 298 K.

Fig. 8. Line weaver - Burk straight for the facilitated extraction phenomenon of Ni(II) by the PIM (PVDF-NTA) [NTA]₀ = 0.01568 M, pH = 4, and T = 298 K.

The values of the slopes and intercepts of the obtained line segments in Figs. 7 and 8 make it possible to determine the parameters K_{ass} and D^* and all obtained values are grouped in Fig 9.

Fig. 9. Evolution graphical representation of the microscopic parameters D^* and K_{ass} relating to facilitated extraction of Cr(VI) and Ni(II) by the PIM (PVDF-NTA).

Analysis the graph in Fig 9 confirms that the PIM-NTA membrane is more efficient for the facilitated extraction of Ni(II) in comparison to the extraction of the Cr(VI). This difference in behaviour is explained by the different values of apparent diffusion coefficient D^* for the two ions. This analysis confirms that the parameters D^* and K_{ass} are specific for each adopted substrate type. The data are certainly related to the structure of the extractive agent NTA which possesses several possible interaction sites, interacting preferentially with the Ni(II) ions substrate, in comparison to the Cr(VI) ions. Consequently, the diffusion of the substrate through the membrane phase according to a mechanism by jumps on fixed sites is more favourable in the presence of Ni(II) than its Cr(VI) counterpart.

4. Conclusion

In this study, we developed and characterized a PIM membrane type, based on polymer supports PVDF and PVP with NTA as extractive agent. Then, this membrane was adopted to perform the various experiments relating to the oriented process of the facilitated extraction and recovery of Cr(VI) and Ni(II) ions substrates from simulated aqueous textile solutions. The established models for this oriented process were validated, macroscopic and microscopic parameters (permeability P , initial flux J_0 , association constant K_{ass} , apparent diffusion coefficient D^*) for this facilitated extraction process of the two substrates across the elaborated membrane were determined.

For this process, the PIM membrane consisting of PVDF as a polymer base and NTA as extracting agent was found to be the most effective for the extraction process of Ni(II) compared to its counterpart Cr(VI).

The overall data indicate that the oriented process mechanism relating to the diffusion through this membrane type (PIMs) for the facilitated extraction and removal of Cr(VI) and Ni(II), is carried out according to successive jumps from one fixed site to another of the extractive agent in the membrane phase.
