Abstract

A general method to access CF$_3$-substituted allenes from propargylic alcohols under Lewis acid catalysis in 1,1,1,3,3,3-hexafluoro-2-propanol (HFIP) as solvent is described. By tuning the reaction time and temperature, the obtained allenes rearrange to 1,3-biaryl-1-trifluoromethyl-1$H$-indenes. By tuning the structure of the propargylic alcohol substrates, a range of trifluoromethylated 2$H$-chromenes were successfully synthesized, with use of catalytic quantities of strong Brønsted acid in HFIP. The present method is therefore highly potent for synthesis of a number of potentially pharmaceutically interesting new trifluoromethylated compounds and produces water as the only stoichiometric byproduct.

INTRODUCTION

Propargylic alcohols represent an attractive class of starting compounds for a number of chemical transformations.$^1$ The direct nucleophilic substitution of propargylic alcohols can result in two types of products: an $\alpha$-substituted alkyne or an allene (Scheme 1a).$^2$ The transformations leading to alkynes are well studied.$^3$ On the other hand, there are few examples of the formation of allenes from propargyl alcohols through carbocationic intermediates.$^4$ Generally, carbocationic
intermediates bearing an adjacent electron-withdrawing group, such as a CF$_3$ group, are difficult to form. They are typically generated from halides or pseudo-halides. In some cases, they have been generated from alcohols in the presence of superstoichiometric quantities of Brønsted or Lewis acids. Catalytic methods for their generation are desirable because substituting hydrogen atoms for fluorine atoms is well known to modulate a molecule’s physico-chemical and pharmaceutically relevant properties, such as its pharmacokinetics and binding affinity. One of the most suitable organic solvents used to carry out reactions involving short-lived carbocations is 1,1,1,3,3,3-hexafluoroisopropanol (HFIP). We recently reported that Bronsted acid catalyzed Friedel-Crafts reactions of α-trifluoromethylated benzylic alcohols proceed with ease via α-trifluoromethyl carbocationic species in HFIP. As a continuation of this research program, we explored the reactivity of α-trifluoromethylated propargylic alcohols in HFIP under Brønsted and Lewis acid catalysis. Here we show that CF$_3$-bearing propargyl alcohols are versatile substrates in dehydroarylative Friedel-Crafts reactions (Scheme 1b), giving access to a number of trifluoromethylated allenes, indenes, chromenes and alkenes. The method is of use for the diversity-oriented synthesis of trifluoromethylated compounds, which are of considerable interest to pharmaceutical research, and produces water as the only stoichiometric byproduct.

**Scheme 1.** HFIP-assisted transformation of α-CF$_3$ propargyl alcohols.
Methods for the synthesis of allenes bearing electron-withdrawing groups, such as keto, carboxy, ester, amide, cyano, sulfone groups have been described. Among them, only a limited number allow access to monoaryl and biaryl mono(CF₃) substituted allenes (Scheme 2a). A single example of the Pd-catalyzed synthesis of triaryl mono(CF₃) substituted allenes is known. To our knowledge, no general catalytic methods allowing access to triaryl mono(CF₃) substituted allenes have been reported so far. Furthermore, methods for CF₃-allene synthesis proceeding via carbocationic intermediates have not been described.

Methods for the synthesis of indenes bearing CF₃-groups at the C1-C3 positions are known but are limited in terms of the substitution patterns that can be achieved. Reported strategies include the treatment of indanones with perfluoroalkyl lithium reagents and the use of α-(trifluoromethyl)allyl alcohols. In general, indenes can be prepared by the isomerization of allenes, but the preparation of CF₃-indenes through the intermediacy of CF₃-allenes, reported herein, had not been described. However, during the preparation of this manuscript, Vasilyev, Nenajdenko, Krasavin and collaborators reported a single example of the conversion of a propargylic alcohol to a CF₃-indene using neat sulfuric or triflic acid as solvent, or zeolites under high pressure and temperature conditions (Scheme 2b). Herein we report the first general method for the synthesis of 1,3-biaryl-1-trifluoromethyl-1H-indenes, which employs a Brønsted acid catalyzed approach under significantly milder conditions. Moreover, by tuning of the reaction time and temperature, the corresponding intermediate triaryl CF₃ allenes can be accessed.
RESULTS AND DISCUSSION

Reaction discovery and optimization. We began our investigations with standard conditions for dehydroarylation reactions of benzylic alcohols in HFIP that were previously established. Instead of direct nucleophilic substitution on the α-CF₃ carbon of alcohol 1, with TfOH as catalyst in HFIP at room temperature we observed the nucleophile attack on γ-carbon and formation of allene 1a (Table 1, entry 1). When the same reaction is conducted at higher temperature (50 °C), the formation of an additional product (CF₃-substituted indene, 2a) was observed (entry 2). Weaker Brønsted acids did not lead to the formation of allene or indene (entries 3-5). The stronger fluoroantimonic acid gave a mixture of allene and indene in an approximate ratio of 11:1 (entry 6). Some Lewis acid catalysts provided the allene, but not the corresponding indene in significant yield (entries 7-11). However, FeCl₃ led to the formation of the allene in 93% isolated yield in 10 min (entry 12). Heating at 80 °C after longer reaction times led to complete transformation to the corresponding indene (entry 13). By testing the same reaction in other solvents (entries 14-16), we confirmed that this reactivity is optimal in HFIP. Iron(II) chloride was not as efficient as iron(III) chloride (entry 17).

Scope of trifluoromethylated allenes. Encouraged by the initial results, the scope of triaryl monotrifluoromethyl allenes was explored (Table 2). The parent 1,1,1-trifluoro-2,4-diphenyl-but-3-yn-1-ol (1) furnished the corresponding allene 1a with mesitylene as nucleophile in 93% yield. Replacement of the phenyl ring A with cyclohexyl (1b) or biphenyl (1c) groups lead to a significant decrease in yield, but with p-tolyl substitution this decrease was less pronounced (1d). However, o-methyl substitution of ring A (1e) or p-methyl substition of ring B (1f) did not influence the yield significantly. p-Bromo substitution of phenyl rings A or B slowed down the reaction (1g and 1h), which could be overcome in most cases by increasing the reaction time (1h). As expected, an electron-withdrawing (p-fluoro) substituent on phenyl ring B had a deactivating influence (1i). However, electron-donating (p-methoxy) groups also led to lower yields, due to rapid subsequent
indene-forming reactions (1j). The same is true when an electron-donating p-methoxy group is present on ring A. For example, attempts to isolate allene 1k could only be accomplished in 27% yield by interrupting the reaction after 5 minutes. In these cases, attempts to isolate the allene by running at the reaction at lower temperatures or under different concentrations were unsuccessful since the subsequent cyclization is more facile than the initial allene formation. Finally, the use of bulkier nucleophiles such as 1,4-diisopropylbenzene also lead to decreased yields (1l-1o) as did less activated (Cl- and F- substituted) nucleophiles (1p-1r). To confirm the structure of the allenes, we obtained an X-ray crystal structure of allene 1s.

Scope of trifluoromethylated indenes. In the next step of the study, the scope of indenes was explored (Table 3). The indenes 2a and 2l were obtained via allenes 1a and 1l in excellent yields. The indenes 2c, 2d and 2f substituted with phenyl or methyl groups were all obtained in excellent yields. When a methoxy group is attached in the para position on the phenyl ring B, the yield of the indene 2j remained high, unlike the case of the para substituted phenyl ring A (2k). The reaction was slowed down when a bromo-substituent was introduced in the phenyl ring B (2n). 1,3,5-Triethylbenzene proved to be a good nucleophile for formation of indenes (entry 2x). By increasing the temperature to 120 °C, it was possible to use 1,3,5-trimethoxybenzene as a nucleophile (entry 2y). However, when a chloro-bearing arene was used, the yield dropped significantly (2s). In the case of indene 2x and 2y, we were unable to isolate the intermediate allene. Generally, attempts to form indenes from propargylic alcohols using weaker arene nucleophiles via allenes were unsuccessful (for example, via allenes 1p-1q), due both to the reduced ability of the nucleophile to capture the propargylic carbocation, as well as the subsequent deactivating effect of the electron-poor arene on the cyclization of the allene intermediate. Even under more forcing conditions, propargylic alcohols bearing a bromide or fluoride on ring A or ring B did not lead to indenes, but instead stopped at the allenes (1g, 1h, 1i, 1o, 1s) previously described in Table 2.

**Access to 2H-2-trifluoromethyl chromenes.** We hypothesized that propargylic alcohols with an o-hydroxyphenyl moiety should give access to corresponding 2H-2-trifluoromethyl chromenes. Chromenes (benzopyrans) are a class of organic compounds that exhibit various biological activities,$^{23}$ especially their trifluoromethylated derivates.$^{24}$ Here, we found that the catalytic use of TfOH gave higher yields than FeCl$_3$. Indeed, when 1,1,1-trifluoro-4-(2-hydroxyphenyl)-2-phenylbut-3-yn-1-ol (3a) was subjected to 10 mol% TfOH/in HFIP,$^{25}$ we were pleased to observe formation of chromene 4a in quantitative yield (Table 4). Other nucleophiles such as durene,
pentamethylbenzene and 1,3,5-trimethoxybenzene proved to be compatible with the reaction conditions (4b-4d). Slight modifications to the electronic properties of the 2-phenyl ring (4e and 4f) or replacement of the 2-aryl moiety with a 2-alkyl group (4g) were tolerated. Furthermore, the tert-butyl-dimethylsilyl ether derivatives 3e’ and 3f yielded the same product as their phenolic precursors (3e), due to an in situ deprotection/cyclization on 1 mmol scale.

**Reactivity of secondary α-trifluoromethyl propargylic alcohols in HFIP.** In light of the successful reactions of tertiary CF₃-propargylic alcohols, we next tested the reactivity of secondary CF₃-propargylic alcohols in the presence of catalytic TfOH. Unexpectedly, by applying the same reaction conditions, a bis-arylated alkene 6a was observed (Table 5). An X-ray crystal structure of the product 6a revealed the Z-geometry of the double bond, as well as a preferred conformation in which the two mesityl units are aligned. A series of para-substituted secondary α-trifluoromethyl propargylic alcohols was tested for Friedel-Crafts reactions with methyl- and methoxy-substituted benzenes as nucleophiles (Table 5). Methyl- (5b) and methoxy-
(5c) substituted propargyl alcohols furnished products 6b and 6c in slightly higher yields than the parent alcohol 6a. Substitution with a cyano-group led to significant loss in reactivity (6d). In addition to the electronic deactivating effect of the CN group, the lowered yield may also potentially be due to the ability of this mildly basic group to buffer the Brønsted acid catalyst. The less electron-withdrawing bromine substituent led only to a minor drop in yield (6e). When 1,3,5-trimethoxybenzene was used as nucleophile, substantially lower yield of 6f was obtained with the parent alcohol 5a. However, methoxy-substituted alcohol 5c furnished the corresponding product 6g in good yield. With other methyl-substituted benzenes, such as p-xylene (6h), pentamethylbenzene (6i-j) and durene (6k), as nucleophiles, reaction products were also obtained in good to excellent yields.

Mechanistic experiments. To determine whether the FeCl₃ acts as a Lewis acid or Brønsted acid catalyst, reactions were carried out in the presence of catalytic quantities (10 mol%) of the hindered Brønsted base 2,6-di-tert-butylpyridine, which does not coordinate most metal ions, and in the presence of a similar amount of Proton-sponge (1,8-Bis(dimethylamino)naphthalene, N,N,N',N'-Tetramethyl-1,8-naphthalenediamine). In both cases, no reaction was observed, suggesting that the role of the FeCl₃ is to generate a hidden Brønsted acid catalyst. However, substituting FeCl₃ with 10 mol% HCl gave only traces of product, excluding HCl as the active catalyst. Therefore, we suspect that the active catalytic species is a partially hydrated or HFIP-bound ferric ion that acts as a Brønsted acid catalyst, although rapid and complex equilibria between many possible species make this very difficult to determine definitively.

Insight into the mechanism of the cyclization of allenes to indenes can be extracted from the observed scope of substrates (Table 3). When a methyl group is in the ortho position on the phenyl ring A, like in the cases of 1e and 1m, the formation of the indene is disabled. Para-bromo substitution in phenyl ring A of the starting alcohols also leads to significantly lower cyclization rates of 1g and 1o. To distinguish whether ring A or ring B are involved in the indene-forming cyclization event, deuterated substrate 1-d₅ was exposed to the standard reaction conditions. Analysis of the ¹H and ²H NMR and high resolution MS of the resulting product revealed its structure to be that of 2a-d₄ as shown in Scheme 3, consistent with a Nazarov-type cyclization involving ring A rather than one involving ring B (Scheme 4). Similar cyclizations have been reported to be catalyzed by Yb(OTf)₃, AgOTf, and TfOH.

![Scheme 3. Reaction of pentadeuterated substrate 1-d₅ with mesitylene](image-url)
Regarding the bis-addition of arenes to secondary propargylic alcohols (Table 5), the proposed mechanism is shown in Scheme 5. First, the hydroxyl group is activated by the TfOH/HFIP hydrogen-bond network, which is followed by nucleophilic substitution at the γ-carbon. Then, the C-C double bond that is more distant from the CF$_3$ group is protonated, forming a carbocation that is both benzylic and allylic. This carbocation is attacked by a second arene molecule, furnishing a tri-substituted allylic trifluoromethane.

**Scheme 5. Plausible mechanism for bis-addition to secondary α-CF$_3$ propargylic alcohols**

**CONCLUSION**

We have described a straightforward catalytic method to access triaryl CF$_3$- bearing allenes, indenes, chromenes and 1,1,1-trifluoro-3-butenes directly from α-CF$_3$ propargylic alcohols. The important role of HFIP solvent in combination with strong Bronsted or Lewis acids such as triflic acid or FeCl$_3$ were key to the observed reactivity. Mechanistic experiments suggest the initial
formation of a CF₃-allene intermediate, which subsequently cyclizes to the corresponding CF₃-indene.

**EXPERIMENTAL SECTION**

**General Information.** All Friedel-Crafts reactions were performed in 10 mL glass pressure tubes under an atmosphere of air. Elevated temperatures were achieved by way of a stirrer-hotplate, metal heating block and thermocouple. Purification of reaction products was carried out by flash column chromatography using Merck silica gel (40-63 μm). Analytical thin layer chromatography (TLC) was performed on aluminum sheets precoated with silica gel 60 F254 (Merck), cut to size. Visualization was accomplished with UV light. ¹H NMR spectra were recorded on a Bruker UltraShield Plus 400 (400 MHz) spectrometer at ambient temperature and are reported in ppm using solvent as internal standard (residual CHCl₃ at 7.26 ppm). ¹³C{¹H} NMR spectra were recorded on a Bruker UltraShield Plus 400 (100 MHz) spectrometer at ambient temperature and are reported in ppm using solvent as internal standard (CDCl₃ at 77.16 ppm). ¹⁹F NMR spectra were recorded on a Bruker UltraShield Plus 400 (376.5 MHz) spectrometer at ambient temperature and are reported in ppm using trifluoroacetic acid as external standard (peak at −76.55 ppm). Data are reported as: multiplicity (ap = apparent, br = broad, s = singlet, d = doublet, t = triplet, q = quartet, quint = quintet, sext = sextet, m = multiplet, dd = doublet of doublets, ddd = doublet of doublet of doublets, dddd = doublet of doublet of doublet of doublets, qd = quartet of doublets, dt = doublet of triplets, dm = doublet of multiplets, td = triplet of doublets, quintd = quintet of doublets), coupling constants (in Hz) and integration. In cases where compounds were isolated as mixtures of regioisomers, signals corresponding to protons of the major regioisomer were integrated as integer values matching the number of protons in the molecule. Non-integer integration values correspond to signals of protons of minor regioisomers or to overlapping signals of regioisomers. GC/MS analysis was conducted on a GC System 7820A (G4320) connected to a MSD block 5977E (G7036A) using Agilent High Resolution Gas Chromatography Column HP-5MS UI, 30 m×0.250 mm×0.25 μm. High resolution mass spectrometry (HRMS) analysis was performed on instruments GCT 1er Waters (EI and CI), MicroTOF-Q Bruker (ESI), and a GC Thermo Scientific Trace 1300 GC unit coupled to an APPI MasCom source mounted on a Thermo Scientific Exactive Plus EMR mass unit (Orbitrap FT-HRMS analyzer). **Materials:** All
commercial materials were purchased from Sigma-Aldrich, Alfa Aesar and FluoroChem, and were used as received, without further purification.

**Preparation of tertiary propargylic alcohols**

**General procedure A for tertiary propargylic alcohols synthesis:** Trifluoromethyl phenyl ketone (5.0-10 mmol, 1.0 equiv) and phenyl acetylene (1.5 equiv) were diluted in 10-15 mL DMSO. CuI (0.10 equiv) and K$_2$CO$_3$ (0.20 equiv) were added and the reaction mixture was heated at 50-70 °C for 24 h. The reaction mixture was then treated with brine, extracted with CH$_2$Cl$_2$, dried with anhydrous sodium sulfate and concentrated at reduced pressure. The product was then purified by silica gel column chromatography.

1,1,1-Trifluoro-2,4-diphenylbut-3-yn-2-ol was prepared according to general procedure A and isolated as a yellow oil. Preparation of allenes

General procedure B: To a 10 mL reaction tube was added the catalyst (10 mol%), HFIP (0.50 M relative to propargylic alcohol), propargylic alcohol (0.17-0.40 mmol, 1.0 equiv), followed by the arene nucleophile (5.0 equiv). The mixture was allowed to stir at 25 °C until judged complete by TLC (9:1 Petroleum ether:EtoAc), typically after 10 min. The reactions typically turn
an opaque black. The crude reaction mixture was directly transferred for silica gel chromatography.

**General procedure C:** To a 10 mL reaction tube was added the catalyst (10 mol%), HFIP (0.5-1.0 M relative to propargylic alcohol), and propargylic alcohol (0.17-0.40 mmol, 1.0 equiv), followed by the arene nucleophile (5.0 equiv). The reactions typically turn an opaque black. After completion of the reaction as judged by TLC, the crude reaction mixture was directly transferred for silica gel chromatography.

Preparation of tertiary propargylic alcohols for synthesis of chromenes

**General procedure D:**

**Step 1.** To a 0.5 M solution of ethynyl magnesium bromide (10 mmol) in THF was slowly added aryl trifluoromethyl ketone (10 mmol) in THF (20 mL). After 3 h at ambient temperature the reaction mixture was quenched first with water and then with saturated Na2SO4(aq). The aqueous layer was extracted with Et2O. The combined organic layers were dried over Na2SO4, filtered and concentrated under reduced pressure to afford colored oil that was used for subsequent synthesis of chromenes.

**Step 2.** To a solution of ethynyl magnesium bromide (10 mmol) in dry THF (20 mL) was added tert-butyldimethylsilyl chloride (20 mmol) in one portion and the reaction mixture was stirred at ambient temperature for 1 h. The mixture was then diluted with CH2Cl2 and filtered through celite. The residue was purified by flash column chromatography (petroleum ether/EtOAc 9:1) to provide the desired product (1-ido-2-(tert-butyldimethylsilyloxy)benzene - compound B). **Step 3.** To a stirred solution of compound B (10 mmol) in Et3N (20 mL) under argon were sequentially added Pd(PPh3)2Cl2 (1 mol %) and CuI (2 mol %) at ambient temperature. Then compound A (1.3 equiv) was added and the mixture was stirred overnight. The reaction was quenched with saturated NH4Cl (aq), extracted with Et2O, dried over Na2SO4, and was purified by flash column chromatography (petroleum ether/EtOAc 9:1). To the isolated product (10 mmol) in THF (20 mL) was added tetra-n-butyl ammonium fluoride (1.2 equiv) at room temperature for 30 min. The reaction was quenched by adding water and extracted with EtOAc, dried over Na2SO4. The crude material was purified by column chromatography (petroleum ether/EtOAc 10:1) to give the pure propargylic alcohol that was used for subsequent synthesis of chromenes.
2-(4,4,4-Trifluoro-3-hydroxy-3-phenylbut-1-yn-1-yl)phenol was prepared according to general procedure D using 2,2,2-trifluoro-1-phenylethen-1-one (1.4 mL, 10 mmol). **General procedure F for preparation of secondary propargylic alcohols.** Secondary propargylic alcohols were prepared via two-step Kitazume/Sato sequence. To a mixture of alkyne
(10 mmol) and anhydrous THF (30 mL) at −78 °C was added n-BuLi (10 mmol, 2.5 M solution) for 5 min. After 20 min stirring at −78 °C, ethyl fluoroacetate (10 mmol), boron trifluoride diethyl etherate (12 mmol), and anhydrous THF (20 mL) were added. After an additional 2 h of stirring, the reaction was quenched with brine, extracted with ethyl acetate, and dried over Na2SO4. The resulting ketone was purified by flash chromatography (petroleum ether/EtOAc 9:1). The ketone was dissolved in methanol (10 mL). To the solution was added NaBH4 (10 mmol) slowly and the reaction solution was stirred for 30 min at room temperature. The mixture was quenched by adding brine and extracted with ethyl acetate, dried over Na2SO4. Finally, purification by flash chromatography yielded the secondary propargylic alcohols.
